2.1 Introduction

The Ptolemy interactive graphical interface (pigi) is a design editor for Ptolemy applications. It is based on tools from the Berkeley CAD framework. In pigi, Ptolemy applications are constructed graphically, by connecting icons. Hierarchy is used to manage complexity, to abstract subsystem designs, and to mix domains (models of computation).

2.1.1 Setup

Ptolemy uses several environment variables (see page 2-51). In order for Ptolemy to run properly, the following two environment variables must be set in your .cshrc file:

- PTOLEMY is the full path name of the Ptolemy installation, and
- PTARCH is the type of computer on which you are running Ptolemy.

Example settings for a .cshrc file follow, along with how to update your path variable:

```bash
setenv PTOLEMY ~ptolemy
setenv PTARCH `$PTOLEMY/bin/ptarch`
set path = ($PTOLEMY/bin $PTOLEMY/bin.$PTARCH $path)
```

When Ptolemy was installed, a fictitious user named ‘ptolemy’ may have been created whose home directory is the Ptolemy installation. If Ptolemy has been installed without
creating a ‘ptolemy’ user, then use the appropriate path name of the Ptolemy installation for
the value of the PTOLEMY environment variable, such as /usr/eesww/share/
ptolemy0.7, for example. Once you make the appropriate changes to your .cshrc file, you
will need to reevaluate the file:

    source ~/.cshrc

In the documentation, we will generally refer to the home directory of the Ptolemy
installation as $PTOLEMY, but sometimes we forget and use ~ptolemy.

Pigi requires the MIT X Window System. If you are not familiar with this system, see
the appendix, “Introduction to the X Window System” on page B-1. Some X window managers
are configured to require that you click in a window before the “focus” moves to that window.
This means that the window will not respond to input just because you have placed the
mouse cursor inside it. You must first click a mouse button in the window. While it is possible
to use pigi with this configuration, it is extremely unpleasant. In fact, it will be rather
unpleasant to use any modern program that makes use of the window system. You will want to
change the mode of the window manager so that the focus follows the mouse. The precise
mechanism for doing this depends on the window manager. For the Motif window manager,
mwm, the appropriate line in the .Xdefaults file is:

    Mwm*keyboardFocusPolicy: pointer

For the open-look window manager, olwm, the line is:

    OpenWindows.SetInput: followmouse

Alternatively, you can invoke olwm with the option -follow. Typically, the window manager
is started in a file called .xinitrc in your home directory.

If you are running Sun’s OpenWindows, you may find that the Athena widgets have
not been installed; pigi will not run without them. See the installation instructions in the
appendix. For more information on using pigi with OpenWindows, see “Introduction to the
X Window System” on page B-1.

2.2 Running the Ptolemy demos

A good way to start is by running a few of the Ptolemy demos. Any user can do this,
although average users are not permitted to change the demos. If you feel compelled to change
a demo, you can copy it to your own directory by using cp -r (see the section below, “Copy-
ing objects” on page 2-44). You can modify the copied version.

2.2.1 Starting Ptolemy

In any terminal window, change to the master demo directory:

    cd $PTOLEMY/demo

Start the Ptolemy graphical interface:

    pigi &

You should get three windows: a vem console window at the upper left of your screen, a pa-
ette with icons of demonstrations below that, and a message window identifying the version of
Ptolemy, as shown in figure 2-1. The borders on your windows may look different, since they
are determined by the window manager that you use. If you have problems starting pigi, see
“Problems starting pigi” on page A-16. A complete list of options that you can specify on the command line is given in the section “Command-line options” on page 2-53. For example, if you are only interested in running the instructional/demonstration version, which only contains the Synchronous Dataflow and Discrete-Event Domains, then evaluate

FIGURE 2-1: If you start pigi in the directory $PTOLEMY, once the system is started you will see these three windows. The upper left window is the vem console window. Below that is a palette of icons representing demo directories. To the right is the Ptolemy welcome window.
pigi -ptiny &

Once you get all three windows, you have started two processes: the graphical editor, vem, and a process named pigiRpc that contains the pigi code and the Ptolemy kernel. The vem window prints the textual commands corresponding to your selections with the mouse. Watching the vem window is useful in diagnosing mistakes, such as drawing a box when you meant to draw a line. The vem console window also displays debugging messages, as well as the error and warning messages that appear in popup windows.

Clicking any mouse button in the welcome window (the one with the picture of Mr. Ptolemy) will dismiss it. Clicking the left mouse button on the “more information” button will display copyright information. The remaining windows can be moved and resized using whatever mechanism your window manager supports. The windows can be closed by typing a control-d with the mouse cursor inside the window. Closing the vem console window will terminate the entire program.

For reference, a summary of the pertinent terms is given in table 2-1 on page 2-4. These will be discussed in more detail as we go.

The palette window contains icons. Five different types of icons are used in pigi, as shown in figure 2-2. The ones in the palette window are of the first type; they represent other palettes. If you have a color monitor, the outline on these icons is purple.

### 2.2.2 Exploring the menus

Place the mouse cursor on the icon labeled “SDF”. Get the pigi command menu by holding the shift key and clicking the middle mouse button. This style of menu is called a “walking menu.” Make sure you hold the shift button. The resulting command menu is shown

</table>

**TABLE 2-1:** Summary of terms defining software components.
The names displayed in the left main menu are only headers. To see the individual commands under each header, you must move the mouse to the arrows at the right of the menu. The submenu that appears on the right contains commands. Clicking any mouse button with a command highlighted as shown on the right will execute that command. To remove the menu without executing any command, simply click a mouse button anywhere outside the menu.

2.2.3 Traversing the hierarchy

Go to the “Window” sub-menu, and execute the look-inside command, as shown above on the right. A new palette will open, containing icons representing further palettes. Look inside the first of these, labeled “Basic”. The icons inside contain application programs, called “universes” in Ptolemy. The two palettes you have just opened are shown in figure 2-3. They are both explained in further detail in “An overview of SDF demonstrations” on page 5-51.

Note in the Ptolemy menu that the look-inside directive has an “i” next to it. This is a “single key accelerator.” Without using the walking menu, you can look inside any icon by simply placing the mouse cursor and hitting the “i” key on the keyboard. The single-key accelerators are extremely useful. In time, you will find that you use the menu only for commands that have no accelerator, or for which you cannot remember the accelerator. The Ptolemy commands obtained through the above menu are summarized in table 2-2. The few commands you will need immediately are shaded in table 2-2.

Look inside the first demo on the third row, labeled “sinMod”. You will see the sche-
matic shown in figure 2-4. Try looking inside any of the icons in this schematic. If you look inside the icon labeled “modulator”, you will see the lower schematic in figure 2-4. If you look inside the icon labeled “XMgraph”, this time, instead of graphics, you will see text that defines the functionality of the block. The syntax of this text is explained in the programmer’s manual, volume 3 of the Almagest. You can change the editor used to display the text by setting an environment variable \texttt{PT\_DISPLAY} (see “Environment variables” on page 2-51).

2.2.4 Running a Ptolemy application

To run the \texttt{sinMod} system using the walking menu, place the mouse cursor anywhere in the window containing the \texttt{sinMod} schematic, i.e., your cursor should be in the window containing the schematic shown in figure 2-4.

**TABLE 2-2:** A summary of the Ptolemy commands in the pigi menu, which is obtained by holding the shift button and clicking the middle mouse button. The single-key accelerators for commands that have them are shown. The commands that are most useful for exploring the Ptolemy demos are shaded.
that contains the following schematic:

Modulation of a sine wave by another sine wave

Again holding the shift key, click the middle mouse button. Go to the “Exec” sub-menu, and select “run” by clicking any button. Notice that typing an “R” would have had the same effect.

FIGURE 2-4: One of the synchronous dataflow demos. This Ptolemy application modulates a sine wave with another sine wave. The upper diagram is the top level. The lower is the contents of the “modulator” subsystem.
The following control panel pops up:

![Control panel for sinMod](image)

If you click the left mouse button on the “GO” button (or hit “return”), Ptolemy will run this application through 400 iterations. When the run is finished, a graph appears, as shown in figure 2-5. Try resizing and moving this display. Experiment in this pxgraph window by drawing boxes; to draw a box, just drag any mouse button. This causes a new window to open with a display of only the area that your box enclosed. Although the new window covers the old, if you move it out of the way, you can see both at once. Any of the now numerous open windows can be closed with a control-d.

### 2.2.5 Examining schematics more closely

Place the mouse cursor in any schematic or palette window, and click the middle mouse button without holding the shift key. The vem command menu, which is different from the pigi command menu, appears. This menu is the same style of “walking menu” as the

![Graph generated by the “sinMod” application](image)

**FIGURE 2-5:** The graph generated by the “sinMod” application in figure 2-4. The graph is displayed by a program called “pxgraph,” based on xgraph by David Harrison.
piqi menu, and is shown below:

The vem menu is used for manipulating the graphical description of an application. The commands obtained through this menu are summarized in Table 2-3, and explained in full detail in Chapter 19.

A few additional window manipulations will prove useful almost immediately. In any of the vem windows, you can closely examine any part of the window by drawing a box enclosing the area of interest and typing an “o”. Like in a pxgraph window, this causes a newwindow to open, showing only the enclosed area. Unlike pxgraph windows, typing the “o” is necessary. In addition, you can enlarge a window using your window manager manipulation, and type an “f” to fill the window with the schematic. You can also zoom-in (or magnify) by typing a “z”, and zoom-out by typing a “Z” (see Table 2-3 on page 2-11). These and other vem commands are referenced again later, and documented completely in chapter 19.

2.2.6 Invoking on-line documentation for stars

You may wish to understand exactly how this sinMod example works. There are several clues to the functionality of the stars. After a while, the icons themselves will be all you will need. At this point, you can get several levels of detail about them. First, you will want to know the name of each star. If you have closed the sinMod window, open it again. Notice the names that appear on each of the icons. In more complicated schematics, when the icons are much smaller, the names will not show. You can zoom-in on a region of the window to see the names. Alternatively, you can place the mouse on any icon and issue the “show-name” command (in the “Other” menu), or type “n”.

Find the singen block at the left of the sinMod schematic. To understand its function, place the mouse cursor on it, and execute the Other:profile command. Here “Other” refers to the command category and “profile” to the command in the submenu (you may also type “;”). This command invokes a window that summarizes the behavior of the block, as shown below:

For some blocks, further information can be obtained with the Other:man\(^1\) (“M”) command,
which displays a formatted manual page. Try it on the XMgraph block at the right of the schematic. The ultimate documentation for any block is, of course, its source code. For the sin-gen block, the source is another schematic. Use the “look-inside” command (using the accelerator key “i”) to see it. Recall that you can also look at the source code of the lowest level blocks (called stars) by looking inside them.

2.2.7 More extensive exploration of the demos

You can safely explore other demos in the palette by the same mechanism. The but-

TABLE 2-3: A summary of the Ptolemy commands in the vem menu, which is obtained by clicking the middle mouse button without holding the shift button. The single-key accelerators for commands that have them are shown. The commands that are most useful for exploring the Ptolemy demos are shaded. More complete documentation can be found in chapter 19, “Vem — The Graphical Editor for Oct” on page 19-1.

1. The man command uses Tycho to display the HTML format star documentation that is automatically generated by the ptlang program.
The terfly demo at the upper left of the “basic” palette in figure 2-3 is particularly worthwhile. The demos in this and other palettes are briefly summarized in “An overview of SDF demonstrations” on page 5-51.

The init.pal palette in figure 2-1 contains icons leading to a top-level demo directory for each domain distributed with Ptolemy. Some of these are labeled “experimental”. These domains largely reflect research in progress and should be viewed as concept demonstrations only. The mature domains have no such label, although even these domains contain some experimental work. A quick tour of the basic capabilities can be had by looking inside the icon labeled “quick tour” in the start-up palette shown in figure 2-1. Each time you encounter a universe, run it.

2.2.8 What’s new

For readers familiar with previous versions of Ptolemy, you may wish to take a tour of the new features only. The “What’s New” icon in the init.pal palette in figure 2-1 leads to such a tour. Look inside it and you will see an icon for each of the last several releases. Open any one and explore the icons therein. Each time you encounter a universe, feel free to run it.

2.3 Dialog boxes

As you explore the demos, you will frequently encounter dialog boxes and control panels. For example, the run command opens a control panel like the one shown above that, among other things, allows you to specify how long the simulation should run. Most of the control panels that you will encounter have been designed using an X window toolkit called Tk, and every effort has been made to follow the Motif design style. Hopefully, this will look familiar to most people.

2.3.1 Tk control panels

Most of the items in a control panel are self-explanatory. Consider the run control panel shown on page 2-9. The button with the double relief (the GO button) is the default button. Hitting the return key has the same effect at clicking the mouse on this button. A different type of button is the “check button”, labeled “Debug”. Clicking on this button expands the control panel, as shown below, giving the user options that are sometimes useful in debugging a complex application.

The “Animation” buttons show (textually or graphically) which blocks are running at any
given time. Graphical animation will dramatically slow down a simulation, so it is not advised except for occasional use. It is often useful in combination with the step button, which will fire stars one at a time.

The early end button terminates the simulation as of the point currently reached, but then it runs the wrapup methods of the stars, just as if the simulation had ended normally. Thus, it is an invasive alteration of the behavior of the simulation. The results displayed during wrapup may be subtly or wildly different from the results that would have been obtained if the simulation had been allowed to proceed to its scheduled end time. Some of the demos will in fact deliver incorrect, or at least unexpected, results if stopped early.

The early end button differs from the abort button in that the early end button calls the wrapup methods, abort does not. Thus, for example, signal plots that normally appear at the end of a simulation will not appear when abort is used.

Clicking on the debug button a second time will reduce the control panel to its previous form.

Many control panels have text widgets. In the control panel above, for example, the box labeled “When to stop” is a text widget. To change the number, you must use Emacs-like editing control characters. These are summarized in table 2-4. In addition, using the mouse, you can position the cursor anywhere in the text to begin editing by clicking the left button. For example, to enter a new number for “when to stop”, position the cursor in the number box and type control-k followed by the new number. You can then push the go button (or type return) to run the application the specified number of iterations.

Many control panels have more than one text widget. The current field is the one with the cursor, and anything you type will go into it. To change the current field to a different one, move the mouse or use the “tab” key to move to the next one.

### 2.3.2 Athena widget dialog boxes

Although we have been working hard to eliminate them, a few old-style dialog boxes based on the Athena widgets from MIT still survive in the system. You will recognize these immediately because they are much uglier and more difficult to work with than the Tk-based
widgets. Here is an example:

![Image of a dialog box with text widgets]

The text widgets in these dialog boxes also use Emacs-style commands. However, do not type return; this adds a second line to the dialog entry, which for most commands is confusing at best. If you accidentally type return, you can backspace sufficiently to get back to one line. Meta-return is the standard way to invoke the “OK” button in these widgets.

2.4 Parameters and states

To see the parameter values of a star or galaxy, execute the Edit:edit-params command, which has the accelerator key “e”. The singen star in the sinMod application has the following parameter screen:

![Image of a parameter screen]

Notice that the frequency parameter is given as an expression, “PI/100” (PI represents the constant \( \pi \)). This section describes the expression language for specifying parameter values.

The parameter screen can be kept open while you experiment with different values of the parameters. Try changing the value “PI/100” to “PI/200”. Click “Apply” in the parameter window, and then “GO” in the run control panel. How does this change the display? Clicking “Cancel” in the parameter window will restore the parameter values to the last saved values and dismiss the parameter window. Clicking “Close” will dismiss the parameter window without restoring the parameter values.

2.4.1 A note on terminology

A State is a data-structure associated with a star and is used to remember data values from one invocation to the next. For example, the gain of an automatic gain control is a state. A state need not be dynamic since its value may not change during the course of a simulation. Technically, a parameter is the initial value of a state. Pigi is responsible for defining parameter values and storing them in the design database.
2.4.2 Changing or setting parameters

The edit-params command in pigi permits the user to set the initial value of a settable state of any star (lowest level block) and to define and set parameters for a galaxy (composite block) or universe (complete application).

Passing parameters through the hierarchy

Star parameters may be linked to the parameters of the galaxy or universe that contains the star. The syntax for linking the values of the star parameters to values of galaxy or universe parameters is simple. Consider again the sinMod application shown in figure 2-4. The parameter screen for the modulator block is shown below:

This block, however, is a galaxy, not a star. If you look inside (as has been done in figure 2-4), and edit the parameters of the singen block inside modulator, you will see

Notice now that the value of the frequency parameter is a symbolic expression, “freq”. This refers to the galaxy parameter “freq”. Thus, parameter values can be passed down through the hierarchy. These symbolic references can appear in expressions, which we discuss next.

Parameter expressions

Parameter values set through pigi can be arithmetic expressions. This is particularly useful for propagating values down from a universe parameter to star parameters somewhere down in the hierarchy. An example of a valid parameter expression is:

\[
\frac{\pi}{2 \times \text{order}}
\]

where order is a parameter defined in the galaxy or universe. The basic arithmetic operators are addition (+), subtraction (-), multiplication (*), division (/), and exponentiation (^). These operators work on integers and floating-point numbers. Currently all intermediate expressions are converted to the type of the parameter being computed. Hence, it is necessary to be very careful when, for example, using floating-point values to compute an integer parameter. In an integer parameter specification, all intermediate expressions will be converted to integers.
Complex-valued parameters

When defining complex values, the basic syntax is

\[(\text{real}, \text{imag})\]

where \text{real} and \text{imag} evaluate to integers or floats.

Fixed-point parameters

Fixed-point parameters may be assigned a precision directly. To do this, the parameter is given in the syntax \("(value, precision)\", where \text{value} is an ordinary number and \text{precision} is given by either of two syntaxes:

- **Syntax 1**: As a string like \("3.2\)”, or more generally \("m.n\)”, where \(m\) is the number of integer bits (to the left of the binary point) and \(n\) is the number of fractional bits (to the right of the binary point). Thus length is \(m+n\).

- **Syntax 2**: A string like \("24/32\)” which means 24 fraction bits from a total length of 32. This format is often more convenient because the word length often remains constant while the number of fraction bits changes with the normalization being used.

In both cases, the sign bit counts as one of the integer bits, so this number must be at least one.

Thus, for example, a fixed-point parameter might be defined as \("(0.8, 2/4)\).” This means that a 4-bit word will be used with two fraction bits. Since the value \("0.8\) cannot be represented precisely in this precision, the actual value of the parameter will be rounded to \("0.75\)\.

A fixed-point parameter can also be given a value without a precision. In this case, the default precision is used. This has a total word length of 24 bits with the number of integer bits set as required to store the value. For example, the number 1.0 creates a fixed-point object with precision 2.22, and a value like 0.5 would create one with precision 1.23.

The precision of internal computations in a star is typically given by a parameter of type \text{precision}. A precision parameter has a value specified using either of the two syntaxes above.

2.4.3 Reading Parameter Values From Files

The values of most parameter types can be read from a file. This syntax for this is to use the symbol < as in the following example:

\(< \text{filename} >\)

First, any parameters appearing in the \text{filename} in the form of \{parameter\} are replaced with their values. Then, any references to environment variables or home directories are substituted to generate a complete path name. Finally, the contents of the file are then read and spliced into the parameter expression and reparsed. File inputs can be very useful for array parameters which may require a large amount of data. Other expression may come before or after the <filename syntax (any white space that appears after the < character is ignored).

2.4.4 Inserting Comments in Parameters

Comments are also supported for non-string parameters. A comment is specified with
the # symbol. Everything after the # until the end of the line is discarded when the parameter is evaluated. Comments are especially useful in combination with files as they can help remind the user of which galaxy or star parameter the file was written.

For example, a comment could be added to the frequency parameter above:

freq # This is set to the Galaxy parameter

Comments are not supported for the String parameter or String Array parameter types. In fact, when the image processing stars use String states to represent a filename, the # character is used to denote the frame number of the image being processed.

2.4.5 Using Tcl Expressions in Parameters

Arbitrary Tcl expressions can be embedded in a parameter expression by preceding the expression with the ! character as in the following example:

! "expression"

First, parameters in the form of {parameter} appearing in the expression are replaced by their values. Then, the string is sent to the pigiRpc Tcl interpreter for evaluation. Finally, the result is spliced into the parameter expression and reparsed. The pigiRpc Tcl interpreter is the same interpreter that appears as a window when pigi is started by using pigi -console.

This facility is general and supports both numeric and symbolic computing of expressions. Through Tcl, one can access all of its math functions, which generally behave as the ANSI C functions of the same name: abs, acos, asin, atan, atan2, ceil, cos, cosh, double, exp, floor, fmod, hypot, int, log, log10, pow, round, sin, sinh, sqrt, tan, and tanh. So, a parameter expression could be

! "expr sqrt(2.0 / {BitDuration})"

for the amplitude of the oscillators in a binary frequency shift keying system, in which BitDuration is a parameter. The expr command is a Tcl command that treats its arguments as a single mathematical expression that must evaluate to a number.

The Tcl mechanism can be used to return symbolic expressions:

! "join 2*gain1"

Because gain1 is not surrounded by curly braces, its value is not substituted before passing the expression to the Tcl interpreter. The Tcl interpreter will return 2*gain1 which is then evaluated by the parameter parser.

Note that whitespace between ! and " is permitted in numeric parameters, but not in string parameters: to get a Tcl call to be recognized in a string parameter you must write:

!"list /users/ptolemy/myfile"

There are several Tcl commands embedded in pigiRpc that help support parameter calculations. They are: listApplyExpression, max, min, range, rangeApplyExpression, and sign. For example,

! "min [max 1 2 3] [sign -2]"

first evaluates to min 3 -1 and then to -1. The procedure range returns a consecutive sequence of numbers:
The rangeApplyExpression procedure generates a sequence of values by applying a consecutive sequence of numbers to a Tcl expression that is a function of $i$. For example, you can generate the taps of an FIR filter that is a sampled sinusoid by using

```
! "rangeApplyExpression { cos(2*{PI}*$i/5) } 0 4"
```

generates one period of sinusoidal function and returns

```
1.0 0.309042 -0.808986 -0.809064 0.308916
```

The listApplyExpression is similar to rangeApplyExpression except that it only takes two arguments: the second argument is a list of numbers to substitute for $i$ in the expression. The command

```
! "listApplyExpression { cos(2*{PI}*$i/5) } [range 0 4]"
```

is equivalent to the previous example of the rangeApplyExpression function.

If you are running Tycho TclShell from within pigi or pigi -console, you can receive help on the new Tcl procedures listApplyExpression, max, min, range, rangeApplyExpression, and sign, by typing

```
help sign
```
at the prompt. To start Tycho from within pigi, type a y while the mouse is over a vem facet or palette.

The Tycho TclShell and the pigiRpc console includes the Ptolemy interpreter (ptcl) which defines the help mechanism. Help is available on all of the commands we have added to the Tcl language.

### 2.4.6 Using Matlab and Mathematica to Compute Parameters

Since Tcl can be used to compute parameters as described in the previous section, Ptolemy’s Tcl interface to Matlab [Han96] and Mathematica [Wol91][Bla92] can be used to compute parameters. This allows even more expressiveness, but the drawback is that demonstrations relying on Matlab and Mathematica will only work at sites that have Matlab and Mathematica installed. For example, we can use Matlab to design an 32-order FIR half-band filter using the Parks-McClellan optimal equiripple FIR filter design algorithm:

```
! "matlab getpairs c {c=remez(32, [0 0.4 0.6 1], [1 1 0 0])}"
```

Similarly, we can use Mathematica to derive formulas to be used as parameters:

```
! "mathematica get c {c=Integrate[A x, {x, 0, 1}]}"
```

This command returns the symbolic expression $A/2$ which is reparsed by Ptolemy. Matlab and Mathematica can be used to keep track of how parameter values are computed. Mathematica can also be used to return symbolic expressions that can be used in conjunction with higher-order functions to define scalable systems [Eva95].

The Ptolemy interface to Matlab and Mathematica can also be accessed from the pigiRpc console window, and the Tycho editor offers console windows that mimic the Matlab and Mathematica teletype (tty) interfaces. More information about the options of the Tcl commands matlab and mathematica can be found by using the help facility described above.
2.4.7 Array parameters

When defining arrays of integers, floats, complex numbers, fixed-point numbers, or strings, the basic syntax is a simple list separated by spaces. For example,

```
1 2 3 4 5
```
defines an integer array with five elements. The elements can be expressions if they are surrounded by parentheses:

```
1 2 PI (2*PI)
```
Repetition can be indicated using the following syntax:

```
value[n]
```
where n evaluates to an integer. An array or portion of an array can be input from a file using the symbol `<` as in the following example:

```
1 2 < filename 3 4
```
Here the first two elements of the array will be 1 and 2, the next elements will be read from file `filename`, and the last two elements will be 3 and 4. This latter capability can be used in combination with the `WaveForm` star to read a signal from a file.

2.4.8 String Parameters

There is a bit of complication when one wishes to set a string parameter or string array parameter equal to the value of a galaxy or universe parameter. This is because a distinction must be made between a sequence of characters that give the name of a symbol and a sequence of characters to be interpreted literally. The syntax to use is explained in the example:

```
This string has the word {word} taken from another parameter
```
Here `{word}` represents the value of a string universe or galaxy parameter. This capability is especially useful for constructing labels for output plots. When using string states to specify options for a Unix command, as in the options parameter in `Xgraph` stars, you can use either double quotes or single quotes to include white space within a single word:

```
-0 'original signal' -1 'estimated signal'
```
String arrays have a few more special restrictions. Each word (separated by white space) is a separate entry in the array. To include white space in an element of the array, use quotation marks. Thus, the following string array

```
first "the second element" third
```
has three elements in it. The string array

```
repeat[10]
```
has ten separate copies of the string “repeat” in 10 separate entries in the array. Curly braces are used to substitute in values from galaxy parameters. Thus, in

```
{paramname}
```
`paramname` must be the name of either a string array or a scalar-valued parameter (an integer, float or complex array, for example, is not permitted). If it is a string array, then each element of `paramname` becomes an element of the parameter. If it is some other kind of parameter the value becomes a single element of the string array.
To use one of [ ], { }, or } literally, quote them with double quotes. To turn off the special meaning of a double quote, precede it with a backslash: ". Similarly, use \ to get a single backslash.

String array values may also be read from files using the < symbol. For details on how to use file references, see section 2.4.3 above. Note that for string arrays, the filename can be a literal string such as

< $PTOLEMY/data/filename

as well as a string that refers to parameters such as

< $PTOLEMY/{data_dir}/data_file

in which case the value of the parameter data_dir would be substituted. Ptolemy does not perform expansion of filenames such as file.{1,2} into file1 file2 as a Unix shell might do.

### 2.5 Particle types

The packets of data that pass from one star to another in Ptolemy are called *particles*. So far, all particles have simply been floating-point numbers representing samples of signals. However, several other data types are supported. Each star icon has a stem for each porthole. In *pigi*, if you are using a color monitor, the color of the stem indicates the type of data that the porthole consumes or produces, as summarized in table 2-5. A blue stem on an input or output of a star icon indicates type “float”, a purple stem indicates type “fix” for fix-point particles, a white stem indicates type “complex”, an orange stem indicates type “int” for integer particles, a green stem indicates “message”, a black stem indicates type “string”, a yellow stem indicates type “file”, and a red stem indicates “anytype”. The “message” type is a user-defined data type (see the programmer’s manual). A star that operates on “anytype” particles is said to be *polymorphic*. Polymorphic stars operate on multiple types of data. For example, a *Printer* star can produce a textual representation of any type of particle. In addition, stars

<table>

</tbody>
</table>

**TABLE 2-5:** Data types supported by the Ptolemy kernel.
which input or output Matrix type particles have stems which are extra thick with colors corresponding to the four main types, float, int, complex, and fix.

Ptolemy usually makes conversions between numeric particle types automatically. The float to complex conversion does the obvious thing, putting the float value into the real part of the complex number and setting the imaginary part to zero. The complex to float conversion computes the magnitude of the complex number. Int to float is easy enough. Float to int rounds to the nearest integer.

The Xscope star, and some other stars that generate output, accept “anytype” of input. However, Xscope isn’t completely polymorphic, because it converts all inputs to float internally. So for a complex input, the magnitude will be plotted. If you want to plot both the real and imaginary parts you should use the ComplexReal conversion star first.

In some situations automatic type conversions cannot be made. A common difficulty involves several outputs of different types feeding a Merge star. Ptolemy must assign a specific type to the Merge star’s output, but in this case it will be unable to decide which type to use, so it will complain that it “can’t determine DataType” for the output. The solution is to insert one or more type conversion stars, so that all the values arriving at the Merge star have the same type. (The type conversion stars can be found in the “conversion” palette of the appropriate domain. It will be explained below how to find this.)

There are no automatic conversions between matrix particles and scalar particles; in fact the matrix particle types do not support automatic type conversion at all. Conversion stars need to be explicitly inserted between two stars that work on different Matrix types.

Some domains are more restrictive about particle type conversions than others. Assignment of types to ANYTYPE portholes and resolution of type conflicts is discussed further in section 4.6 of the Ptolemy Programmer’s Manual, and in the Ptolemy Kernel Manual.

### 2.6 The oct design database and its editor, vem

With the experience gained so far, it may be helpful to explain more clearly the software architecture of the system. Pigi is built on top of existing CAD tools that are part of the Berkeley CAD framework. An important component of this framework is oct, which serves as the design database. Oct keeps track of block connections, parameter values, hierarchy, and file structure, and hence moderates all accesses to designs stored on disk. The organization is shown in figure 2-6. Vem is an interactive graphical editor for oct. Vem provides one of many ways to examine and edit designs stored by oct. This chapter gives just enough information about vem to use it with Ptolemy in simple ways. More complete documentation is contained in chapter 19, “Vem — The Graphical Editor for Oct” on page 19-1.

In pigi, the Ptolemy kernel runs in a separate Unix process, called pigiRpc, attached to vem. Users edit designs using vem, store their designs using oct, and execute their application through the link to the Ptolemy kernel. The two Unix processes are shown in the shaded boxes in figure 2-6. The user interacts with both processes but only the user interface of the pigiRpc process has been upgraded to use Tcl/Tk, as explained above. With this software architecture in mind, we can now define terms that we have been using informally.

Oct objects (which are stored on disk) are called facets. A facet is the fundamental unit that a user edits with vem. As an analogy, we can think of a facet as a text file in a com-
puter system and vem as a text editor, such as vi or emacs. However, instead of calling system routines to access the data stored in a text file like vi does, vem calls oct routines to access the data stored in a facet. Thus, oct manages all data accesses to facets. Facets may define a universe or a galaxy, for example. Thus, figure 2-4 on page 2-8 shows a facet that defines a universe and a second one that defines a galaxy.

Facets may also define the physical appearance and formal terminals of icons that represent stars, galaxies, universes, and wormholes, e.g., the physical appearance of each icon in figure 2-4 is defined in another facet called the interface facet. A schematic that uses icons, by contrast, is called a contents facet. The “edit-icon” command (“I”) will open the facet defining an icon. Instructions for modifying the appearance of an icon are given in “Editing Icons” on page 2-34.

A facet may also contain a palette, which is simply a collection of disconnected icons. Palettes are directories of stars, galaxies, and universes in a library. Thus, for example, figure 2-3 on page 2-6 shows two palettes, both of which contain sets of icons. Note that facet names, like file names in Unix, should not contain spaces.

### 2.7 Creating universes

If you are following this chapter sequentially, then you still have Ptolemy running from previous sections. To see how Ptolemy will behave when started in your own directory, exit pigi. Do this by typing a control-d character in the vem console window. A dialog box may appear with a menu of facets that vem thinks have been changed. Since all of these belong to the user “ptolemy”, you do not want to save them. If it appears, do not select any of them. Just click “OK”. A warning window may then appear telling you that closing the console window will terminate the program. Just click “Yes”.

In this section, we will show how to create your own universes with a simple example that is very similar to the sinMod demo explored above. First, be sure you are in a directory where you have write permission, like your home directory.

![Diagram](https://example.com/diagram.png)

**FIGURE 2-6:** The software architecture of the Ptolemy design environment running under pigi, the graphical interface. The user interacts with two Unix processes, pigiRpc and vem.
• Create a new work area:

```
mkdir example
cd example
```

• Start pigi:

```
pigi
```

You will see the message:

```
creating initial facet "init.pal"
```

Wait until the welcome window with the picture of Ptolemy appears. We are now ready to learn about the basics of using vem.

### 2.7.1 Opening working windows

Now we are ready to create a simple universe. Let’s create a simulation that generates a sine wave and displays it.

- Open a new facet: The facet that is already open, called “init.pal”, is special because pigi always opens a facet by this name in the directory in which it starts. Convention in Ptolemy dictates that “init.pal” should be used to store icons representing complete applications, so instead of using this facet, we will create a new one.

  - Place the cursor in window labeled “init.pal:schematic”.

  - Select the open-facet command from the “Window” pigi menu (shift-middle-button). Alternatively, type an “F”. You will get a directory browser that looks like this:

```
- Replace the name “init.pal” in the text widget with “wave” and click the “OK” button (or hit the return key). A quick way to delete the “init.pal” is using control-u. A new blank window will appear.
• Open a palette:
  - Place the cursor in either blank window.
  - Select the *open-palette* command from the “Window” *pigi* menu. Alternatively, type an “O”.
  - *Pigi* will present a palette menu. Select the “sdf” palette by clicking the left button in the box next to “$PTOLEMY/src/domains/sdf/icons/main.pal” (the first entry) and then click on “OK”.
  - The palette that opens is shown on the left of figure 2-7. This palette shows the basic categories of synchronous dataflow stars that are available. There are too many stars to put in just one palette. You can use the Window:look-inside (“i”) command to open any of the palettes. At this point you should look inside the “Signal Sources”, “Nonlinear Functions”, and “Signal Sinks”. Arrange these palettes on the screen so that you can see the blank window labeled “wave”. The stars and palettes are summarized in “An overview of SDF stars” on page 5-4.

2.7.2 Some basic *vem* commands

At this time, it is worth exploring some basic *vem* commands for manipulating window displays. *vem* uses post-fix commands. This means that the user enters the arguments to a command before the command name itself. Arguments appear in the *vem* console window as the user enters them. Note that although the text of what the user enters is displayed in the console window, the cursor should be in one of the facet windows.

There are several types of arguments. Each argument type is entered in a different way. All graphics arguments are created with the left mouse button. The five types of arguments are listed below:

Point: Position the cursor, click the left mouse button.

Box: Position the cursor, drag\(^1\) the left mouse button.

Line: Make a point, position the cursor on the point, and drag the left mouse button.

Object: Use *select-objects* and *unselect-objects* commands (explained later).

Text: Enclose text in double quotes.

Arguments can be removed from the command line by typing the delete key, backspace key, or “control-u”, which deletes all the current arguments. There are three ways to enter commands:

Menus: Click the middle-button for *vem* commands, shift-middle-butt-

---

1. “Drag” means to press down on a mouse button, move the mouse while holding it down, and then release the button.
ton for \texttt{pi\_gi} commands. Menus are of the “walking” variety, as explained before.

**Key bindings:** Commands can be bound to single keys and activated by just pressing the key. Key bindings are also called “single-key accelerators”, and are case sensitive. The key bindings are summarized in table 2-2 on page 2-7 and table 2-3 on page 2-11.

**FIGURE 2-7:** The master palette for the stars in the SDF domain (left) and one of the sub-palettes (right). The subpalette shows “sources” (signal generators). The palettes are explained in more detail in “An overview of SDF stars” on page 5-4.
Type-in: Type a colon followed by the command name. This is rarely used by Ptolemy users, but vem experts use it occasionally.

Let’s try a few examples, some of which should be familiar by now. Place the cursor in one of the palette windows (containing library stars) and:

- Type “shift-Z” (capital Z) for zoom-out. This makes everything smaller.
- Type “z” (lower-case z) for zoom-in. This makes everything bigger. If you zoom in sufficiently, labels will appear below each icon giving the name of the star. vem does not display these labels if they would be too small.
- Try “p” for pan. Pan moves the spot under the cursor to the center of the window.
- The vem pan command can also take as an argument a point which will indicate the new center of the window. Recall that the argument must be entered first. Place a point somewhere in the palette window by clicking the left button, and type “p”. The location of your point became the center of the window.
- The vem open-window command can take a box as an argument. Draw a box in the palette window by dragging the left mouse button and then type “o”, or find the open-window command in the vem menu.
- Try placing points in the new window. Notice that they also appear in the original palette window. Also notice that you are only permitted to place points at certain locations. vem has an implicit grid to which points snap. The default snap resolution is suitable for making Ptolemy universes.
- You can get rid of your point (or any argument list) by typing “control-u”. You can delete arguments one-at-a-time by typing “control-h”. Try placing several points and then deleting them one by one.
- You can close the new window (or any vem window) with “control-d”.
- A particularly useful command at this time is show-all, or “f”. This rescales and recenters the display so that everything in the facet is visible. Try this command in the palette window that you have been working with.
- You can also resize a window, using whatever X Window bindings you have installed, and then type “f” to rescale the display to fill the window.

2.7.3 Building an example

- Create an instance of the star called “Ramp”. This star is at the upper right of the sources palette. Its icon has an orange triangle. To do this:
  - Put the cursor in the window “wave:schematic”.
  - Create a point anywhere in the window by clicking the left button.
  - Move the cursor over the “Ramp” icon in the palette and press the “c” key. This is a key binding that executes the vem “create” command.
- You have just created an instance of the “Ramp” icon. The actual data that describes how the “Ramp” icon should be drawn is stored in another facet (an “interface facet”). An instance of the “Ramp” icon points to this facet.

- Delete and select instances: Sometimes in the process of editing your schematic, you may need to delete objects. As an example, let’s create another Ramp instance and then delete it.

  - Create another Ramp instance next to the first one: place a point near the original Ramp, place the cursor over the Ramp icon in the palette and press “c”. Actually, you don’t have to use the icon in the palette — you could also put the cursor over the already existing Ramp icon to achieve the same effect.

  - Place the cursor over the new Ramp icon and execute select-objects by typing “s”. This creates an object argument on the vem command line. This is necessary because the vem delete-objects command takes arguments of type “object”. The select-objects command takes point, box, and/or line arguments and turns the items underneath them into object arguments. The unselect-objects command (“u”) does the reverse of select-objects.

  - Execute delete-objects by typing “D” (upper-case!). This deletes the objects we selected previously.

  - You could also have deleted the newly created Ramp with the undo command (“U”). This is an infinite undo, so you can backtrack through all changes you have made since starting the vem session by repeatedly executing the undo command.

  - Occasionally when you use the select and unselect commands, the objects are not redrawn correctly. When this happens, use the vem redraw-window command, “control-l” (lower case L), to redraw.

- Create the remaining instances in our example:

  - Create an instance of the “Sin” icon to the right of the Ramp. “Sin” is in the “nonlinear” palette, where icons are arranged alphabetically by name. Make sure it does not overlap with the Ramp icon. If it overlaps, you can delete it and create a new one.

  - Create an “XMgraph” instance to the right of the Sin icon. “XMgraph” is the first icon in the first row of the “sinks” palette.

We now have three icons: a Ramp, a Sin, and an XMgraph. Your facet should look something
like this:

Next, we will connect them together.

- Connect the Ramp output to the Sin input using the following steps:
  
  - With the mouse cursor in the “wave” window, type “f” to show all. This will rescale your system, and make it easier to make connections.
  
  - Draw a line between the output of the Ramp and the input of the Sin: put the cursor over the Ramp output, double-click on the left mouse button, drag the cursor to the Sin input, and then let up on the mouse button. If the two terminals are not on a horizontal line, you can bend the line by momentarily releasing the mouse button while dragging it.
  
  - Type “c” (for create) to create a wire. Notice that the create command creates wires or instances depending on the type of arguments it is called with.
  
  - If you need to delete a wire, you can draw a box around it (click and drag with the mouse), select it (press “s”), and then delete it (“D”).

- Connect the Sin output to the XMgraph input in a similar way.

- Run the universe: We now have a complete universe that we can simulate.
  
  - Execute the run command from the pigi “Exec” menu, or type an “R”.
  
  - Enter “100” for “When to stop”. Do this by typing “control-u” to remove the default entry in the text widget and typing 100. This specifies that the system should be run through 100 “iterations”. What constitutes an iteration is explained in chapter 5, “SDF Domain” on page 5-1. For this simple system, it is just the number of samples processed.
  
  - Clicking on the GO button or typing a return character will run the system.

A new window with a graph of a rough sine wave should appear. The system generates the sine wave by taking the sine of a sequence of increasing numbers generated by the Ramp star. The execution of the XMgraph star created this new window to show the output of our simulation. To remove this window, click on the “Close” button or press “control-d” in it.

- Save the facet by typing “S” (upper-case) with the cursor in the “wave” window. This
executes the \texttt{vem save-window} command. It is wise to periodically save your work in case the editor or computer system fails unexpectedly.

- Change parameters: If we look at the output, the sine wave appears jagged. This is because the \texttt{Ramp} star has a set of default parameters which cause it to generate output values with an increment that is too large. We can change the parameters of as follows:

  - Place the cursor over the \texttt{Ramp} icon and execute \texttt{edit-params} in the \texttt{pigi} menu (or type “e”). A dialog box will appear that shows the current parameters.

  - Replace the value of \texttt{step} with “PI/50”. (You can use “control-u” to erase the old value.) Finally, click the “OK” button to store the new parameters. This is an example of Ptolemy’s parameter expression syntax, explained above.

- Run the simulation again using 100 iterations. This time the output should look like one cycle of a reasonably smooth sine wave.

- Use \texttt{save-window} again to save the new parameters.

To be able to conveniently access this example again, you should create an icon for it. We will do this with the \texttt{pigi} command “\texttt{Extend:make-schem-icon}”, or “@”.

- Place the mouse cursor in the “wave” facet window, and hit the “@” key. A dialog box appears asking for the name of the palette in which you would like to put the icon. By convention, we put universe icons in palettes called “init.pal”. So replace the default entry (which should be “./user.pal”) with “init.pal”. When the icon is made, find the “init.pal” window that first opened when you started the system, and type “f” to show all. It should look like this:

```
Looking inside this icon (“i”) will get you your “wave” facet. The second item in the palette is a marker indicating where the next icon that you create will go. Henceforth, anytime you start \texttt{pigi} in this same directory, the first window you will see will be this “init.pal” window.

- Our example is now complete. To exit:

  - Close all pxgraph windows with “control-d”.

  - Type “control-d” in the \texttt{vem} console window. If nothing needed to be saved, the program exits immediately. Otherwise, a dialog box appears asking you to choose buffers to be saved. Unfortunately, as of this writing, some of the buffers listed may have already been saved and do not need to be saved again. The program is overly cautious. To indicate which of the listed buffers you wish to
save, click on the box to the left of each name. Then click on the “OK” button.

- A final warning appears telling you that closing the console window will terminate the program. Click on “Yes”.

2.8 Using galaxies

In this section we will explain how to create galaxies. Galaxies allow you to use hierarchy to partition your design into more manageable pieces and to re-use designs as components in other designs.

2.8.1 Creating a galaxy

Use the schematic we created in the last example to make a sine wave generator galaxy.

- Instead of modifying our previous example, we will make a copy of it. In your “example” directory, type:
  \[ \text{cp -r wave singen} \]
  The recursive copy, \text{cp -r}, is necessary because \text{oct} stores data using a hierarchical directory structure. Of course, if the facet \text{singen} exists already, you must remove it with \text{rm -r} first before copying.

- Start \text{pigi}.

- Use \text{open-palette} (or “O”) to open the “$PTOLEMY/lib/colors/ptolemy/system” palette (the last one in the list of palettes). The system palette contains input and output ports which can be instantiated into schematics just like stars. The contents of the palette are shown below:

- Use \text{open-facet} (or “F”) to open the “singen” you created using “\text{cp -r}”. You can use the file browser shown on page 2-23; just double click on the name “singen” in the lower window of the browser.

- In the “singen” window, delete the \text{XMgraph} star and the wire attached to it. The easiest way to do this is draw a box (click-drag) around the star and its input wire, press “s” to select these objects, and then press “D” to delete them. (You may want to enlarge your window to make it easier to work.)

- Place an output port where the \text{XMgraph} star used to be and connect it to the output of the \text{Sin} star. The output port is the icon in the system palette with an arrowhead (an input port, by contrast, has a fish tail), as shown above.

- Name the output port “out”:
  - Position the cursor over the black box on the new output port.
- Type “out” as a text argument, including quotation marks.

- Type “c” for create. Again, note that the create command has a different action than before. It names input or output terminals when given a text argument.

We now have a galaxy. The fact that a schematic has input or output ports distinguishes it as a galaxy. This galaxy that you just created is similar to the “singen” galaxy in the “Signal Sources” palette. Find it, and look inside, to make the comparison.

2.8.2 Using a galaxy
We have just created a galaxy that we would like to use in another design. In order to do this, we need to create an icon for this galaxy that we will then instantiate in our other design.

- Create an icon:
  - Place cursor in “singen:schematic” window.
  - Execute make-schem-icon in the pigi “Extend” menu (“@”).
  - The dialog box should contain:
    Palette: ./user.pal
    This specifies the name of the palette that will contain your icon. By convention, we usually put galaxy icons in the palette called “user.pal” in the current directory. Hence, this is the default name.
  - Since you had already created an icon for the “wave” universe, and that icon was copied by your cp -r, vem asks whether it is OK to overwrite the icon. Click “OK”. Wait until make-schem-icon is done. Vem informs you that it is done with a message in the vem console window, which may be buried by now.

- Open the palette called “user.pal” using open-palette (“O”). The newly created galaxy icon should appear in this palette along with the same special icon we saw before, called a cursor. A cursor distinguishes a palette from other types of facets and it determines where the next icon will be placed.

- At this point, we have an icon for our sine wave generator galaxy. It is this icon facet that is instantiated in the “user.pal” palette. We can now use our sine generator galaxy simply by instantiating our icon into another schematic.

- Use open-facet to create a new facet with the name “modulation”.

- In the “modulation” window, create a universe that takes two “singen” galaxies, multiples their outputs together, and then plots the result using “XMgraph”. The “XMgraph” star can be found again in the “Signal Sinks” subpalette of the SDF palette. The multiplier star, called Mpy, is in the “Arithmetic” subpalette.

**Hint:** If you place the icons so that their terminals fall on top of one another, then a connection
gets made without having to draw a wire.

- Now run the universe with “when to stop” set to 100. The output should appear as a squared sine wave, which is just a sine wave of twice the frequency shifted up by 1/2.

So far, we have created a galaxy and used it in another universe. But we could also have used our galaxy within another galaxy. In this way, large systems can be broken up into smaller more manageable pieces.

### 2.8.3 Galaxy and universe parameters

One of the problems with the “singen” galaxy that we just created is that it generates sine waves with a fixed frequency. We would like to make the frequency of the generator parameterizable. That way, we could set the two “singen” galaxies in our “modulation” universe to two different frequencies.

To make a galaxy parameterizable, we create **formal parameters** in the galaxy and then link the formal parameters to the **actual parameters** of the instances contained in the galaxy. The terms, “formal” and “actual” parameters, are analogous to formal and actual parameters in any procedural programming language. An example will make this clear.

- Create formal parameters:
  - Place the cursor in the “singen” window but away from any instance, i.e., in the grey background of the facet.
  - Execute `edit-params` (“e”). An empty parameter window will appear, looking like this:

![Parameter Window](image1)

To add parameters to the galaxy, click on the “Add parameter” button. A window appears looking like this:

![Add Parameter Window](image2)

Fill in the dialog as follows:
name: freq
    type: float
    value: PI/50

The value will be the default value. Then click on “OK”. Recall that you can use “tab” to move from one field to the next of the dialog box and “Return” instead of “OK”. Hence, the dialog can be managed from the keyboard without requiring the mouse.

We just created a new formal parameter called “freq” with a default value of “PI/50”. Additional parameters may be added or old ones changed. The default value of a formal parameter can always be changed by executing edit-params in the background of the galaxy. Executing edit-params on the icon representing the galaxy changes the parameter values only for the instance represented by the icon. It overrides the default value specified in the background of the galaxy definition. The possible types for parameters are listed in table 2-6. The syntax for specifying values for parameters is described above in “Changing or setting parameters” on page 2-15. Exactly the same procedure can be used to attach formal parameters to a universe. This allows you to parameterize a complete Ptolemy application.

- Link formal parameters to actual parameters:
  - Place the cursor over the Ramp icon in the singen window.
  - Execute edit-params and fill in the dialog as follows:
    
    \[
    \begin{align*}
    \text{step: freq} \\
    \text{value: 0.0}
    \end{align*}
    \]

    This allows the freq parameter of a singen instance to control the increment of the internal ramp star, thus controlling the output frequency.

- Change the frequency of one of the singen instances to “PI/5” by using edit-params. This singen will be ten times the frequency of the other.

- Run the universe with an iteration of 100. The output should show the product of two sine waves with different frequencies. Don’t forget to save the facets we just created.

TABLE 2-6: Parameter types supported in Ptolemy
would also be a good idea to create an icon for modulation and put it in init.pal.

2.9 Editing Icons

Pigi automatically generates icons for stars and galaxies, respectively, when you invoke the make-star or make-schem-icon command from the Extend menu. Pigi puts the new icon in a user-specified palette, which by default is user.pal in the directory in which you started pigi. More or less any vem manipulations can be performed on this icon, but some guidelines should be followed. These icons have a generic symbol, shown in figure 2-2 on page 2-5. To change it, place the cursor over the icon and execute the edit-icon (“I”) command in the pigi menu. A new window containing the icon will appear.

Recall from section 2.6 on page 2-21 that icons are stored in interface facets and that the icons that appear in contents facets are really instances of icons. These instances merely refer to the actual icon facet. The edit-icon command opens a window into the actual icon. Any changes made in this window will affect the appearance of all instances referring to the icon.

Recall also that icon facets store a different kind of data from other facets. Icon facets contain information that tells vem how to draw objects. Hence, a different set of commands must be used to edit icons. Whenever you edit an icon, vem switches to a different mode called “physical editing style.” In this mode, we create objects such as lines, boxes, and polygons. This is in contrast to “schematic editing style” which we used before to create instances and connect them together with wires. Physical editing style shares many commands with schematic editing style. For example, select-objects is active in both modes. A list of useful physical editing style commands and their key bindings is given in table 2-7.

The commands that create geometry expect a layer argument. The layer of an object determines its color and its fill pattern. To specify a layer, place the cursor over an object attached to the desired layer before executing a command. You can open a palette of layers with the palette (“P”) command. The palette is shown in figure 2-8.

The layer palette contains several columns of solid and outline colors, with the name of the color at the top of the column. Colors at the top of each icon will be layered on top of colors below them in the columns. A set of special layers are arranged at the bottom of the palette. The layers for icon stems are explained below. The layers for icon bodies define the icon background and optional icon shadow.

A few simple notes will help greatly. First note that when the icon window is opened, the snap is automatically set to 5 “oct units”. This is because the default snap for schematic windows, normally 25 units, is far too coarse for most icon editing functions. A reasonable compromise is 5 units, unless you are going to try to create a very elaborate icon, in which case 1 unit is probably what you want. The vem Options:window-options command allows you to change the snap.

When editing an icon, the vem menu is slightly different than when you are editing a schematic. In vem terminology, this is because you are working with the physical view of a facet. The commands are shown in table 2-7. Most icons can be created by experimenting with the following operations:

1. You must have write permission on the facet to change the icon.
- Select the default symbol within the icon that Ptolemy created when it created the icon

**TABLE 2-7:** A summary of the Ptolemy commands in the vem menu in icon editing mode. These commands are obtained by clicking the middle mouse button without holding the shift button when your mouse cursor is in an icon window. The single-key accelerators for commands that have them are shown. More complete documentation can be found in chapter 19, “Vem — The Graphical Editor for Oct” on page 19-1. The command that differ significantly from those in table 2-3 are shaded.
(a star, galaxy, cluster of galaxies, or palette symbol, as shown in figure 2-2 on page 2-5). You can do this by drawing a box (drag the left mouse button) and typing “s” (or using Selection:select-objects in the menu). You can unselect with “u” or control-u. An alternative selection method is to place a point and type “s”. This usually provokes a dialog box to resolve ambiguities. Delete whatever parts of the icon you don’t want using “D” or Selection:delete-objects. WARNING: Do not delete terminals! If you accidentally delete a terminal, the easiest action is begin again from scratch, asking pigi to create a new icon.

- Bring up the vem color palette by typing “P” (or System:palette in the menu). You will get the window shown in figure 2-8.
- Draw a line by clicking the left button to place a point, and pushing and dragging the mouse button from the same point. Then move the mouse to desired color in the color palette and type “c” (or Edit:create-geometry from the menu). A line may consist of multiple line segments by just repeatedly pushing and dragging the mouse button.
- To create filled polygons, place points at the vertices, then type “c” on the appropriate solid color in the palette.
- To create a circle, place a point at the center, a point on periphery, and type “C” on the appropriate color. To create a filled circle, use a line segment instead of a pair of points.
- Objects can be moved by selecting them, dragging the mouse (using the right button) to produce an image of the object in the desired place, and typing “m”.
- You may change (or delete) the label that pigi automatically puts at the bottom of the icon. To change it, select it and type “E” (Edit:edit-label in the menu). The resulting

![Image of a color palette](image-url)

**FIGURE 2-8:** The palette of colors and layers that can be used to create icons. This palette is invoked by the “palette” vem command (“P”). Each color has a column of boxes. The higher the box you use, the closer to the front an object will be. The colors at the bottom are special, in that they are associated with particular data types.
dialog box is self explanatory. The standard Emacs-like editing commands apply.

- **BE SURE TO SAVE YOUR ICON.** This can be done by typing “S” (System:save-window in the **vem** menu). You can close your window with control-d. Note that **vem** buffers the data in the window. You can close it and reopen it without saving it, as long as the session has not been interrupted.

By convention, the data types supported by a terminal are indicated by the color of the stem that connects the terminal to the body of the icon. The following colors are currently in use:

- **ANYTYPE:** red
- **FLOAT:** blue
- **INT:** brown
- **FIX:** purple
- **COMPLEX:** white
- **PACKET:** green
- **FILE:** yellow
- **STRING:** black

The color is currently set automatically by the icon generator by using layers defined specifically for this purpose, called **anytypeColor**, **floatColor**, **intColor**, **fixColor**, **complexColor**, **packetColor**, **stringColor** and **fileColor**. These colors are shown at the bottom of the color palette in figure 2-8.

You can change the color of an object manually, if you wish. To do this, select the object, type “"xxxx"”, where xxxx is replaced by the color name (the quotation marks are necessary), and then type the single character “l” (an el — or **Edit:change-layer** in the menu). Be sure not to change the color of a terminal! Again, be sure to save the window.

One final editing operation is a little trickier: moving terminals. **Pigi** places terminals rather arbitrarily, since it knows nothing of their function. You may wish to have a smaller icon than the default, in which case you have to move the input terminals closer to the output terminals. Or may wish to change the order of the terminals, or you may want to have terminals on the top or bottom of the icon rather than right or left. All of these can be done, but the following cautions must be observed:

- **Do not move terminals of icons that have already been used in applications.** Unfortunately, if you do this, the block will become disconnected in all applications where it is used. If you are tempted to move terminals in a commonly used block, consider the tedium of finding all applications (belonging to all users) and reconnecting the block. **ONLY MOVE TERMINALS ON BRAND NEW ICONS.**

- **You must respect the default snap of 25 for schematic windows, and move terminals to a point that falls on a multiple of 25 units.** Otherwise, connecting to the terminal will be very difficult. Normally, when the icon window opens, the grid lines are 10 units apart. So you can place terminals any multiple of 2.5 grid lines away from the center.

- **To orient terminals so they are aiming up or down, select the terminal, type “t” (or **Selection:transform** in the menu), then type “m” to move it.** Repeatedly typing “t” will continue to transform (rotate) the terminal.

A little more detail on the **oct** internals may be useful if you explore the files that are created by these operations. For make-schem-icon, if the schematic is called **xxx**, then the icon itself is
stored in “xxx/schematic/interface;”. The semicolon is part of the filename (this creates some interesting challenges when manipulating this file in Unix, since the Unix shell interprets the semicolon as a command delimiter). The standard stars that are normally part of the Ptolemy distribution are stored in “$PTOLEMY/src/domains/dom”, where dom is the domain name such as sdf or de. The icons for the stars are stored in a subdirectory called icons, the icons for demo systems in a subdirectory called demo, and the source code for the stars are stored in a subdirectory called stars. Feel free to explore these directories.

Changing the number of terminals in galaxy icons

Whenever the contents of a galaxy are changed so that the new definition has different I/O ports, the icon must be updated as well. You can do this by calling make-schem-icon again to replace the old icon with a new one. vem will not allow you to overwrite the old icon if you have instances of the old icon in any open window (regardless of whether the window is iconified). Hence, you must either close those windows with “control-d” or delete the offending icon before replacing it with a new icon. Note that changing number of terminals will also change their layout, so that connections in existing schematics may no longer be valid.

2.10 Sounds

On some workstations (currently only SGI Indigos, HP 700s and HP 800s and Sun SparcStations,), Ptolemy can play sounds over the workstation speaker. Below we discuss various details about playing sounds on various workstations.

2.10.1 Workstation Audio Internet Resources

Below we list several workstation audio resources on the Internet.

ftp://ftp.cwi.nl/pub/audio
Home of the audio file format FAQ.

http://orbit.cs.engr.latech.edu/AF
The AF program is an audio server similar to the X server which allows remote machine to play audio on the local machine. The user starts the AF program in the background and then uses the aplay program to play sounds. AF is not directly supported by Ptolemy, but is nonetheless useful.

http://www.spies.com/Sox/
The sox program converts files between various formats.

The workman program can play audio CDs on Sun SparcStations.

2.10.2 Solaris

Sun workstations running Solaris2.x can play 8kHz mu law sounds directly through /dev/audio. The Solaris2.x /usr/openwin/bin/audiotool program can be used to control the record and play volume and the input and output sources. In Ptolemy 0.7 and later, the SDF Play star writes the appropriate .au file header.
Most Sun workstations can only play 8 bit u-law audio at 8kHz. Sun UltraSparcs can play a range of audio formats: 8 bit u-law, 8 bit A-law and 16 bit linear. UltraSparcs can also play a range of sample rates, including CD (44.1kHz) and DAT (48kHz).

The Solaris /usr/demo/SOUND contains sample sounds and programs. See /usr/demo/SOUND/bin/soundtool for a graphical sound program with a slightly different interface. For further information about audio on Sun workstations, see the man pages in /usr/demo/SOUND/man, and the man pages for audioamd, audiocs, dbri, sbpro, audio, and cdio.

SparcStation CD-ROM

The workman program can play audio CD’s via the Sun SparcStation CD-ROM drive. workman can be configured to use the Solaris volmgmt program so that when an audio CD is inserted into the drive it is automatically played. Only the Sparc5 and a few obscure Sparc10s can get audio from the CD directly. Most other Sparcs can use a mini jump plug from the headphone jack on the CD-ROM to the line in on the back of the machine. You can then use audiotool to control the inputs and outputs. Look under the Volume menu button for the proper controls. It may take a few minutes to adjust the levels appropriately. The workman program can be used as an audio source with the CGC Tycho demos (see “Tycho Demos” on page 14-27) to demonstrate the various audio effects.

2.10.3 HPUX

Under HPUX10.x, the /opt/audio/bin/audio_editor program can play sounds. Under HPXU9.x, use /usr/audio/bin/audio_editor.

2.10.4 Playing Audio over the Network

If you use Ptolemy to create audio files, then you may want to share them with others over the network. There are several ways to play audio over the network, we discuss them below.

Via the Web

Audio files can be placed on HTML pages and played by many HTML browsers over the network. There are many proprietary commercial server packages that allow users to listen to audio via their browser, we do not cover those packages here, instead we discuss two common formats: .au and .wav. In general, SparcStations can directly play only .au files and Windows and Macintosh machines can play both .au and .wav files. If you use Ptolemy to generate a .au file, the file must have a proper header. The SDF Play star will generate that header for you.

Under Solaris, you can use the xplaygizmo and AudioFile aplay programs to play audio files via a browser. To set this up, place the following in the .mailcap file in your home directory and restart your browser.

```bash
audio/*; xplaygizmo -p -q /usr/sww/AF/bin/aplay; stream-buffer-size=2000
```

On the Macintosh to play the .au files under Netscape, you may need to install a sound program. If you are using the “Berkeley Internet Kit”, then you probably already have installed a program SoundApp that can play the Sun audio files. However, Netscape may not
be configured to use it. You can change this by selecting General Preferences from the Options menu, and selecting the Helpers page within that. Under ULAW audio, you should set the file type to ULAW and the application program to SoundApp.

Java

Java can play .au files over the net, but again, these files must have a proper header.

AF

The AudioFile program AF is a audio server that allows a user to listen to a sound generated on a remote machine. See the link above for more information.

2.10.5 Ptolemy Sounds

You can try playing sounds with the universe you just created. Replace the XMgraph star in waveform window with an instance of the Play star (second row of the sinks palette, right of center, with a stylized loudspeaker as an icon). Edit the parameters of the Play star entering 16000 for the gain parameter. (To see details about the Play star, execute the “profile” command in the “Other” menu, or type a comma (",") with the mouse on the Play icon).

The SPARCstation’s speaker is driven by a codec that operates at an 8 kHz sample rate. So running this universe for 40000 samples will produce about 5 seconds of sound. The sound produced by the current parameters is not particularly attractive. Experiment with different parameter values. Try PI/1000 in place of the PI/50.

An interesting variant of this system modulates a chirp instead of a pure sinusoid with a low frequency sinusoid. A chirp is a sinusoid that sweeps over a frequency range. You could replace one of your sinegen instances with something that generates a chirp, and again experiment with parameters.

A chirp can be created with three stars: a Ramp, an Integrator and a Sin, connected in series. The step parameter of the Ramp should be very small, such as 0.0001. With this value, you will hear some aliasing if you create five seconds of sound. The Integrator is in the “arithmetic” palette, furthest on the right, and its default parameter values are fine for this purpose. Use the “profile” command (",") to read about it. Note that a fourth star, a Const (second star in “sources” palette) is needed to set the Integrator reset input to zero.

In the SDF domain, sound output is collected into a file, and then played out in real time. Another alternative, available in the CGC domain, is to generate the output in real-time. Since the CGC stars have not been optimized for real-time performance, only simple signals can be generated at this time.

This is a good time to try out your own examples. In general, when you create new galaxies and universes that depend on each other, it is a good idea to keep them together in one directory. For example, all of the facets we have created so far are in the “example” directory. You can use the extensive Ptolemy demos as models.

2.11 Hardcopy

There are several options for printing graphs and schematics developed under Ptolemy. The first option generates a PostScript description and routes it to a printer or file. The second uses the screen capture capability of the X Window system.
2.11.1 Printing oct facets

A block diagram under \texttt{pigi} is stored as an \texttt{oct} facet. To print it to a PostScript printer, first save the facet. Do this by moving the mouse to the facet and press the “S” key to save. The facet must be saved. Then, keeping the mouse in the facet, invoke the “print facet” command from the “Other” \texttt{pigi} menu. You will get a dialog box that looks like this:

Most entries are self-explanatory. The default printer is determined by your environment variable \texttt{PRINTER}, which you can set by putting the following line in your \texttt{.cshrc} file:

\begin{verbatim}
setenv PRINTER printername
\end{verbatim}

You will have to restart \texttt{pigi} for this change to be registered.

If you select the option “To file only”, then PostScript code suitable for importing into other applications will be generated. The image will be positioned at the lower left of the page. The facets displayed in this document were generated this way and imported into FrameMaker. See chapter 18, “Creating Documentation” on page 18-1 for more information.

The “EPSI” option will create Encapsulated Postscript output. Note that you need to have GNU ghostscript installed to generate EPSI. See “Other useful software packages” on page A-14 for further information about GNU ghostscript.

2.11.2 Capturing a screen image

Under the X window system and compatible systems, there are facilities for capturing screen images. These can be used directly with Ptolemy. However, colors that work well on the screen are not always ideal for hardcopy. For this reason, two sets of alternative colors have been devised for use with black and white printers, these color sets are selected at startup with the \texttt{pigi} command line option \texttt{-bw} or \texttt{-cp}. For black and white printers, use the \texttt{-bw} command line option when starting Ptolemy, as in:

\begin{verbatim}
Ptolemy -- bw
\end{verbatim}

1. PostScript is a registered trademark of Adobe Systems Inc.
The screen capture command can be used effectively. For example, under the X Window system, the following command will print a window on a black and white PostScript printer:

```
xwd | xpr -width 4 -portrait -device ps -gray 4 | lpr
```

If you wish to grab the window manager frame, then you can use:

```
xwd -frame > myfile.xwd
```

Other alternatives include a program called xgrabsc or some equivalent that may be available on your windowing system. A simple use of this is to generate an encapsulated PostScript image using the following command:

```
xgrabsc -eps -page 4x2 -o mySchematic.ps
```

where “mySchematic.ps” is the name of the file into which you would like to store the EPS image. Then with the left mouse button, draw a box around the desired portion of the screen. This command will then save an encapsulated PostScript file four inches by two inches called mySchematic.ps. This file can then be used on a wide variety of document processing systems. To grab an entire window, including whatever borders your window manager provides, use the xgrabsc -click option.

**Importing an image as PostScript**

For example, to include this PostScript in a TeX document, include the command

```
\include{psfig}
```

in the TeX file and use the commands

```
\begin{figure}
  \centerline{
    \psfig{figure=mySchematic.ps,width=4in,height=2in}}
  \caption{Ptolemy Schematic}
\end{figure}
```

To display the PostScript as a figure within a FrameMaker document.

The “print-facet” command can optionally generate a PostScript file suitable for inclusion in a FrameMaker document. Once you have generated this file, the preferred way to include it is as follows. First, create an anchored frame by using the "Anchored Frame" menu choice under the "Special" menu. The anchored frame will contain two disconnected text columns, one for the figure, the other for the figure paragraph that describes the figure. Create the first disconnected text column using the graphics tools. Then, put in the text box a \include line. For example, the text box might contain the following line:

```
#include /users/ptolemy/doc/users_man/figures/butterfly.ps
```

Unfortunately, the file must be specified using an absolute path, unless you always start FrameMaker from the same directory. With the cursor in the newly created text column, issue the command “Customize Text Frame” from the “Customize Layout” submenu in the “Format” menu, and select “PostScript code.” When you print the document, you will get the fol-
The graphic will be anchored at the lower left of the text column you created.

The second disconnected text column is created in a similar fashion with the Graphics tool, but text is entered into the text column rather than the include directive.

It is possible, instead of using the \#include line as above, to directly import the PostScript file into FrameMaker. However, this makes the text document very large, and the FrameMaker process appears to grow in size uncontrollably. Unfortunately, as of this writing, it does not appear possible to convert these PostScript files to encapsulated PostScript, which would have the advantage of displaying a semblance of the image.

**Importing an Image as a X bitmap (XBM)**

FrameMaker and some other text processing systems can import and print ordinary color X window dumps. To have these displayed in color on the screen, the following lines may need to appear in your X resources file:

```
Maker.colorImages: True
Maker.colorDocs: True
```

One can use various programs, such as the FrameMaker 3.1 utility `fmcolor` and the Poskanzer Bitmap (PBM) tools to reduce a color window dump to a black and white window dump. This will save space and avoid any dithered imitations of color. However, since `fmcolor` applies a threshold based on color intensity to the image, some foreground colors may get mapped to white instead of black. To prevent this, use the `-cp` (`cp` stands for color printer) command line option when starting `pigi`, as in

```
pigi -cp
```

Then color window dumps can be converted to black and white window dumps using the following FrameMaker 3.1 command:

```
fmcolor -i 90 filein fileout
```

A useful hint when using such a document editor is to turn off the labels in `pigi` before capturing the image, and then to use the document editor itself to annotate the image. The fonts then will be printer fonts rather than screen fonts. To turn off the labels, execute the `vem` command “layer-display” under the `vem` “Options” menu.
2.12 Other useful information

In this section we cover additional information which may be useful. More advanced topics will be covered in following chapters.

2.12.1 Plotting signals and Fourier transforms

The Ptolemy menu has a submenu called *Utilities* that invokes some useful, frequently used, predefined universes. For example, the “plot-signal” (“~”) command will plot a signal. The signal can be read from a file or specified using the syntax for specifying the value of a *floatarray* parameter in *pig*. For example, if the value of the *signal* parameter is:

\[ 1 \ [10] \ -1 \ [10] \]

then the “plot-signal” command will plot ten points with value 1.0 and ten points with value -1.0. The *options* parameter can accept any options understood by the pxgraph program (see the pxgraph section of the *Almagest*). To plot a signal stored in a file, simply use the following syntax for the *signal* parameter:

\[ < \text{filename} \]

You may need to specify the full path name for the file.

Another useful *Utilities* command is *DFT* (“^”), which reads a signal just as above and plots the magnitude and phase of the discrete-time Fourier transform of the signal. These are plotted as a function of frequency normalized to the sampling rate, from $-\pi$ to $\pi$. The sampling frequency is assumed to be $2\pi$. A simple phase unwrapping algorithm is used to give more meaningful phase plots. A radix-2 FFT is used, so the order (the number of points) of the fast Fourier transform must be a power of two. That is, the user actually specifies $\log_2(\text{order})$. The order can be longer than the signal, in which case, zero-padding will occur.

2.12.2 Moving objects

Sometimes you may want to move objects around within your schematic. Use the *vem* command *move-objects* (“m”) in the *Selection* menu to do this. You can move objects as follows:

- Select the objects that you want to move.
- Using the right mouse button, drag the objects to the desired location.
- Execute *move-objects*, “m”.

2.12.3 Copying objects

You can create a new instance of any object in a facet by placing a point where you want the new instance, moving the mouse to the object you wish to copy, and executing “create” (“c”). However, this does not copy the parameter values. If you wish to create a new instance of a star or galaxy that has exactly the same parameter values as an existing instance, you should use the *vem* *copy-objects* (“x”) command in the *vem* “Selection” menu. To do this, first select the object or objects you wish to copy. Then place a point in the center of the object. Then place a second point in the location where you would like the new object, and type “x”. The new object starts life selected, so you can immediately move it, or type “control-u” to unselect it. As of this writing, *vem* unfortunately does not allow you to copy objects from one
facet to another.

2.12.4 Labeling a design

It is often useful to annotate a block diagram with titles and comments. The `vem edit-label` ("E") command in the “Edit” menu will do this. It takes two arguments: a point specifying the position of the label, and the name of a layer, which determines the color of the label. Place a point where you would like the label, and then type a layer name, such as “blackSolid” (with the quotation marks). Then type “E”. An Athena widget dialog box like that on page 2-14 will appear, offering various options. Type the text for your label in the “Label” box. It can contain carriage returns to get more than one line of text. To select a text height (font size) you can move the slider to the right of the “Text Height” box. The middle button moves the slider by large amounts, and the left and right buttons are used for fine tuning. The initial default is 40, in releases earlier than Ptolemy 0.6, the default was 100, which was too big for all but the loudest titles. Sizes 60 and 40 work well with the overall scaling of Ptolemy facets. You can also change the justification by clicking the left button to the right of each justification box. A pop-up menu lists the options. The colors recommended for labels are:

- blackSolid
- blueSolid
- brownSolid
- greenSolid
- orangeSolid
- redSolid
- violetSolid
- whiteSolid
- yellowSolid

2.12.5 Icon orientation

Most Ptolemy icons have inputs coming in from the left and outputs going out to the right. To get better looking diagrams, you may sometimes wish to reorient the icons. This can be done with the `vem` command “transform” (“t”). Select the icon you wish to transform and type “t” as many times as necessary to get the desired orientation. Each time, you get a 90 degree rotation. Then execute the move-object “m” to commit the change. Notice that a 180 degree rotation results in an upside down icon. To avoid this, reflect the icon rather than rotating it. To reflect it in the vertical direction (exchanging what’s on top for what’s on the bottom), select the object, type “my” (include the quotation marks), type “t” to transform, and “m” to move. To reflect along the horizontal direction, use “mx” instead of “my”. In summary:

To reflect an object horizontally, select it, and type:

```
"mx" t m
```

To reflect it vertically, type:

```
"my" t m
```

2.12.6 Finding the names of terminals

Some stars have several terminals, each with a different function. The documentation may refer to these terminals only by name. Unfortunately, the name of a terminal is not nor-
normally visible when an icon is viewed with normal scaling. However, zooming in will eventually reveal the name. The easiest way to do this is to draw a box around the terminal and open a new window with the “o” command. Then you can zoom in if necessary. Future versions of Ptolemy will hopefully have a better mechanism.

2.12.7 Multiple inputs and outputs

Ptolemy supports star definitions that do not specify how many inputs or outputs there are. The Add and Fork stars are defined this way, for instance. Consider the following two icons, found in the “arithmetic” palette of the SDF domain:

They both represent exactly the same star, as you can verify with the “look-inside” command. The icon on the right, however, has a peculiar double arrow at its input. This is a “multiple input” terminal that allows you to connect any number of signals to it. All the signals will be added. The icon on the left has two ordinary input terminals. It can add only two signals. Why have both kinds?

Sometimes, multiple input terminals are not convenient. A rather technical reason is given below, in the section “Auto-forking” on page 2-48. A more mundane reason is simply that schematics often look better with two-input adders.

There are three ways to work with a star that has a multiple-input or multiple-output connection (technically, a “multiporthole”).

First, you can just draw multiple connections to or from the double-arrow porthole icon. This is easy, but it has some limitations. You can’t control what order the connections will actually be made in. That doesn’t matter for an Add star, but for some star types it’s important to know which connection corresponds to which element of the multiporthole. Also, the connected portholes can’t be connected to any other stars, nor can you use delay icons, because vem will get confused (see “Auto-forking” on page 2-48).

Second, you can attach a “bus create” or “bus break out” icon to the multiporthole terminal, choosing one that provides the right number of terminals for your schematic. (These icons are available in the “Higher order functions” section of the domain’s palette.) This solves both of the problems with multiple connections to a single terminal. It may not make for a very pretty schematic, however.

Third, you can make a custom icon for the star that replaces the double-arrow terminal with the right number of simple terminals. This is what the two-input Add icon actually is. This method takes the most work but may be worth it to make the nicest-looking schematic.

Let’s go through an example of how to create a star icon that has multiple input terminals based on an existing Ptolemy star that supports multiple inputs. Suppose you need an icon for an adder with eight inputs. As of this writing, unfortunately, you need to have write permission in the directory in which Ptolemy icons are stored to create this new icon. Alternatively, you can create your own version of the star in your own directory (see the programmer’s manual). If you have write permission in the directory where the icons are
stored, then you can create a new icon with eight inputs as follows.

In any facet, execute the **pigi** command “Extend:make-star” (“*”). A dialog box appears. Enter “Add.input=8” for the star name, “SDF” for the domain, and “$PTOLEMY/src/domains/sdf/stars” for the star src directory (assuming this is where the source code is stored). Note that “input” is the name of the particular multiple input that we want to specify. If you do not know where the source code is stored, then just look-inside (“i”) an existing instance of the star. The **vem** console window and the header of the editing window that open both tell where the star source code is. A second dialog box appears asking you where you would like the icon put. Accept the default, “.user.pal”. Then open user.pal using “O” to see the new eight-input adder icon. You may edit this icon, as explained in “Editing Icons” on page 2-34.

### 2.12.8 Using delays

In several domains, delays can be placed on arcs. A delay is not a star, but rather is a property of the arc connecting two stars. The interpretation of the delay in the dataflow domains (SDF, DDF, BDF, and most code generation domains) is as an initial particle on the arc. An initial particle for the scalar data types is one whose value is zero. When the arc passes particles containing “message” type data, a delay on the arc will create an “empty” message. Most often, the destination star of the arc must be able to interpret such “empty” messages explicitly in context of the user-defined type because a “zero” might have different meanings depending on the type. Any feedback loop in the SDF domain must have a delay, or the computation in the loop would not be able to begin.

To use these delays in **pigi**, the user places a delay icon on top of the wire connecting two instances. The delay icon is a white diamond with a green border in the SDF and system palettes. You can specify the number of delays by executing *edit-params* with the cursor on top of the delay icon.

Other domains (besides dataflow) also use delays, but the meaning can be quite different. See the appropriate chapter describing the domain.

A new feature added to Ptolemy releases greater than 0.5 is the support of initializable delays for simulation domains. These delays use a different icon from the old white diamond with green borders. The new delays use an icon that is a green diamond with a white border and has an “I” in the middle of the diamond to signify that it is initializable. We have kept around the old delays for backward compatibility, but the syntax for the two is quite different and the user should probably use just one type to prevent confusion.

The syntax for the new delays is that the arguments to the delay are the initial value themselves. There is no value in the argument that signifies the number of delay particles. Instead, a count of the number of values in the delay arguments is the number of delay particles that will be added to the buffer of the arc corresponding to the delay. These arguments are specified as a string and are parsed according to the data type associated to the arc. For example, an initializable delay with parameter “1 0 1” on an arc passing float particles will have a buffer with three initial particles. The three particles will have the values 1.0, 0.0, and 1.0 respectively. If the arc was working on complex particles instead, an error would be given since complex numbers must be specified using a pair of numbers. A proper argument list for the delay in that case would be “(1,0) (0,0) (1,1)”. The shorthand for declaring multiple values in the argument list is valid, just as in the arraystate case. For example, an argument list of “2
[5]” would specify five initial particles with value 2.

Initializable delays also work on arcs which handle matrix particles. The argument string in this case is parsed differently than above. The first two values in the last specify the number of rows and columns in the initial matrix, respectively. For example, an initializable delay with parameter “1 2 3 [2]” on an arc passing integer matrices would place one matrix with dimension one row by two columns, whose entries all have the value three, in the buffer for that arc. For the case where multiple initial matrices are desired, simply give enough entries in the delay argument string to fill multiple numbers of initial matrices of the given size. For example, an initializable delay with parameter “1 2 3 4 4 5 5” on an arc passing integer matrices would create three matrices, all of dimension one row by two columns, such that the first initial matrix on the buffer has all entries equal to three, the second has all entries equal to four, and the last matrix has all entries equal to five.

2.12.9 Auto-forking

In pigi, a single output can be connected to any number of inputs, as one would expect. The interpretation in most domains is that the one output is broadcast to all the inputs. There are several point-to-point connections, therefore, represented by the net.

However, there are restrictions. To understand these restrictions, it is worth explaining that vem stores connectivity information in the form of netlists, simply listing all terminals that are connected together. If a delay appears somewhere on a net, and that net has more than one point-to-point connection, then it is not easy to determine for which connection(s) the delay is intended. Consequently, at the time of this writing, delays are disallowed on nets with more than one connection. If you attempt to put a delay on such a net, then when you try to run the system, an error message will be issued, and the offending net will be highlighted. To get rid of the highlighting, execute the pigi command “Edit:clear-marks”. To fix the problem, delete the offending net, and replace it with one or more fork stars and a set of point-to-point connections. An incorrect and correct example are shown below:

Incorrect

Correct

This example also illustrates the use of a delay on a feedback loop. The delay is required here, assuming we are in the SDF domain, because without it, deadlock would ensue. This is due to the fact that the fork star cannot fire until the add star does, but the add star cannot fire until the fork star produces its output.

A second restriction is that forks must be explicit when connected directly to input or
output terminals of a galaxy. An incorrect and correct example are shown below:

There is also a more subtle restriction. Suppose two outputs are connected to a single multiple-input terminal. Then neither of these outputs can also be connected to some other input terminal. If they are, Ptolemy will issue the error message “multiple output ports found on the same node.” The reason this happens is simple. *vem* knows nothing about multiple inputs, so it sees a net with more than one output and more than one input. Ptolemy is not given enough information to reconcile this and figure out which outputs should be connected to which inputs. To avoid this problem, it is again necessary to use explicit fork stars, as shown below:

Another solution, which may look nicer than inserting an explicit fork star, is to replace the multiple-input terminal with several simple terminals. You can do that by inserting a “bus create” icon or by using a different icon for the multiple-input star, as was explained in “Multiple inputs and outputs” on page 2-46.

All of the above restrictions may be eliminated in future versions.

2.12.10 Dealing with errors

Ptolemy is composed of several components, as shown in figure 2-6 on page 2-22. When errors occur, it helps to know which component detected the error so that it can be corrected.

When errors occur in *vem*, *vem* prints the error in the console window. For example, if you enter a point argument and execute *create* when the cursor is not over an instance, then *vem* displays the message “Can’t find any instance under spot.” Usually, *vem* errors are easy to fix. In this case, *vem* expects the user to specify the instance to be created.
Errors in the pigiRpc process can occur when any of the pigi commands are invoked. The error messages, in this case, are displayed in a popup window, which is much more helpful. Error messages may also be displayed in the xterm window in which pigi was started. In addition, pigi often highlights in red the object in the schematic associated with the error. When this happens, you can execute the clear-marks command to clear the highlighting. If such an error occurs and the reason for the error is not obvious, try deleting the indicated objects and redrawing them.

2.12.11 Copying and moving designs

In one of our examples, we used `cp -r` to make a copy of a facet. In general, however, copying entire designs this way does not work. For it to work in the general case, you must also change some data in the facets that you copy. In particular, each facet has pointers to the icons it uses. If you move a galaxy, for example, then any pointer to the icon for that galaxy becomes invalid (or “inconsistent” in oct terminology).

A utility program called masters has been provided for this purpose. This replaces the program from the octtools distribution, called octmvlib, that was used with earlier versions of Ptolemy.

Palettes, star icons, galaxies, and universes are stored as oct facets. Special care is required when moving or copying oct facets. First, as emphasized before, every oct facet is stored as a directory tree, so a copy should use `cp -r`. Next, keep in mind that there may be pointers to the moved object in other facets. If you know where all these pointers might be, then moving facets is easy. If you do not know where all the pointers are, then your only practical choice is to leave a symbolic link in place of the old location pointing to the new.

Moving facets

Suppose you have developed a fantastic new galaxy called alphaCentaur, and you wish to install it in a directory that is available for general use. Since you have developed the galaxy, you know where it is used. The galaxy icon itself is stored in two facets:

```
alphaCentaur/schematic/contents;
alphaCentaur/schematic/interface;
```

The first of these stores the schematic, the second stores the icon. The peculiar semicolon at the end is actually part of the file name. First move the icon:

```
mv alphaCentaur destinationDirectory
```

This moves the entire directory tree. You must now change all references to the icon so that they reflect the new location. Suppose you have a test universe called alphaTest. This should be modified by running the masters program as follows:

```
% masters alphaTest
```

Running masters on wave
Pathname to replace (? for a listing):

User input is shown in bold type; program output is shown in regular (not bold) type. Enter a question mark to get a list of all icons referenced in the facet:
Pathname to replace (? for a listing): ?
Pathnames currently found in the facet:
~yourname/oldDirectory/alphaCentaur
$PTOLEMY/src/domains/sdf/icons/Ramp
$PTOLEMY/src/domains/sdf/icons/Sin
$PTOLEMY/src/domains/sdf/icons/XMgraph

The last three items are pointers to official Ptolemy icons. There is no need to change these. You should now enter the string you need to replace and the replacement value:

Pathname to replace (? for help): ~yourname/oldDirectory
New pathname: ~yourname/destinationDirectory

Next, use masters the same way to modify any palettes that reference the moved icon. For instance, the “user.pal” palette in the directory in which you developed AlphaCentaur is a likely candidate. If you miss a reference, oct will issue an error message when it tries to open the offending palette, indicating that it is inconsistent.

2.12.12 Environment variables

The following environment variables can be set to customize certain behavior. These should be set (normally) in the user’s .cshrc file.

PIGIBW This variable tells Ptolemy to display all of its windows in black and white.

PIGIRPC Specifies an alternative executable file for Ptolemy. Ptolemy is an extensible, modifiable system. Many users will wish to create their own versions to incorporate their own extensions. Details on how to write extensions are given in the programmer’s manual, volume 3 of the Almagest. Once you (or someone else) has created a customized version, you can invoke it by specifying the precise name of the executable (complete with its full path, or path relative to an environment variable or user’s name). The default executable is $PTOLEMY/bin.$PTARCH/pigiRpc. An alternative specification might be:

```
setenv PIGIRPC ~myname/Ptolemy/bin.sol2.5/pigiRpc
```

PT_DISPLAY Determines the text editor used to display text files. This determines how text files will be displayed to the user. The value of this variable is a printf format string with one %s in it. That %s is replaced with the name of the file to be viewed. In the default, the PT_DISPLAY variable is not set, and the Tycho editor is used. For example, to view files in a new xterm window with the vi editor, put the following line in your .cshrc file:

```
setenv PT_DISPLAY "vi \%s \""xterm -e \"vi \%s \"\"
```
setenv PT_DISPLAY "xterm -e vi %s"

and source the file before starting pigi.

PTARCH  This variable specifies the computer architecture you are using such as sol2.5. The architecture setting is returned by the $PTOLEMY/bin/ptarch script.

PT_DEBUG  If set, this specifies the script to execute when starting pigi in debug mode (using the -debug option). An example of a suitable script is ptgdb, located in $PTOLEMY/bin. This script invokes gdb, the Gnu debugger, inside emacs.

PTMATLAB_REMOTE_HOST  This variable, if set, specifies the name of a remote machine on which to run Matlab if Ptolemy ever invokes Matlab.

PTOLEMY  This variable points to the root directory of where Ptolemy is installed.

PTOLEMY_SYM_TABLE  This variable is an internal symbol that is used during dynamic linking.

PTPWD  This variable gives the command to print the current working directory, which is usually pwd.

TYCHO  This variable points to the root directory of where Tycho is installed.

Ptolemy is based on Tcl and [incr Tcl]. These packages set the following environment variables: TCL_LIBRARY, TK_LIBRARY, ITCL_LIBRARY, ITK_LIBRARY, and IWIDGETS_LIBRARY. See $PTOLEMY/bin/ptsetup.csh.

Below we discuss a few Unix system environment variables that affect how Ptolemy functions.

DISPLAY  Specifies what X11 Display Ptolemy should start up on. If you are unfamiliar with $DISPLAY, then see “Introduction to the X Window System” on page B-1.

GCC_EXEC_PREFIX
    C_INCLUDE_PATH
    CPLUS_INCLUDE_PATH
    LIBRARY_PATH
These variables are used by the Gnu compilers to find components of the compilers, see “Gnu Installation” on page A-7.

HOME  This variable points to the root directory of the user’s account. This variable must be set for itclsh and the software that uses itclsh (ptcl and tycho) to work properly.

LD_LIBRARY_PATH  This variable is used by the run time linker to find shared libraries. If you are using prebuilt binaries, and your Ptolemy installation is not at
The Almagest

/users/ptolemy, then you may need to set this variable, see “pigi fails to start up, giving shared library messages” on page A-17. See also your Unix ld man page, and “Shared Libraries” on page D-1.

**PATH**

This variable contains a list of directories of executable programs. The order of the directories listed is very important. See $PTOLEMY/.cshrc for guidelines on the proper order.

**PRINTER**

Determines the default printer used for hardcopy output. This is used to determine the default printer when printing vem facets. If you use the provided makefile to print Ptolemy documentation, then this environment variable will determine the printer used. In $PTOLEMY/.cshrc the pertinent line reads:

```bash
setenv PRINTER lw
```

You should replace lw with whatever printer name you are using.

**SHLIB_PATH**

Hewlett-Packard systems use SHLIB_PATH instead of LD_LIBRARY_PATH to find shared libraries. See the LD_LIBRARY_PATH description above for details.

**USER**

This variable gives the name of the user running Ptolemy. This variable is set by every shell. In your .cshrc file, add the following line:

```bash
if (! $?USER) setenv USER $LOGNAME
```

Many of Ptolemy’s domains rely on additional environment variables. The CG56 domain relies on S56DSP to indicate the path name where the tools for the S56X Motorola 56000 board are installed and QCKMON to indicate the path name where the QCK Monitor tools are installed. The VHDL domain relies on SYNOPSYS to indicate the root directory for the installation of Synopsys tools and SIM_ARCH to be set to the computer architecture you are using for the Synopsys tools.

### 2.12.13 Command-line options

The pigi program is actually a csh script, located in $PTOLEMY/bin. That script starts two processes: vem and pigiRpc. The usage is

```bash
pigi [options] [facet-name]
```

The optional facet name specifies a vem facet that should be opened upon starting the system. The command-line options are:

- `-bw` Use black and white, even on a color monitor. This is useful for generating readable hardcopy from X Window dumps.

- `-cp` Fine tune the colors to improve the quality of hardcopy made on a color printer from X Window dumps.

- `-console` Open a command console through which the user can issue Tcl commands.

- `-debug` Invoke Ptolemy running under gdb, a symbolic debugger. If a version of the pigiRpc executable with debug symbols can be found, the script will it. If
$PIGIRPC$ is set then that binary is used. If $PIGIRPC$ is not set, then the program first looks for

$PTOLEMY/bin.$PTARCH/pigiRpc.debug

If that is not found, then the program looks for

$PTOLEMY/obj.$PTARCH/pigiRpc/pigiRpc.debug

If that is not found, then

$PTOLEMY/bin.$PTARCH/pigiRpc

is used. If the PT_DEBUG environment variable is set, then its value is the name of a script used to invoke the debugger. For example, the script ptgdb, located in $PTOLEMY/bin, invokes gdb under emacs.

-pto Invoke the smallest version of Ptolemy, if it can be found. The executable that is used is called pigiRpc.ptiny. This version contains only the SDF and DE domains, but without the image processing stars and the user-contributed stars.

-pttrim Invoke an intermediate-sized version of Ptolemy, if it can be found. The executable used is called pigiRpc.ptrim. This version contains only SDF, BDF, DDF, DE, and CGC domains, but without the parallel targets.

-display display-name
Specify an alternative display to use. If this option is missing, then the DISPLAY environment variable is used.

-help print out the usage information

-rpc ptolemy-executable
Specify an alternative Ptolemy executable to use. The default is $PTOLEMY/bin.$PTARCH/pigiRpc.

-xres X-resource-filename
Specify an X resource file to merge before running Ptolemy. The standard X program xrdb is used with the -merge option.

2.13 X Resources

A large number of X window resources can be set by a user to customize various aspects of the user interface. The best way to explore these is to examine the file $PTOLEMY/lib/pigiXRes9 for the defaults. These defaults can typically be overridden in the user's.Xdefaults file, and incorporated into the X environment using the program xrdb. For example,

\texttt{Vem*font: *-times-medium-r-normal-*--120--*}

changes the font in the \texttt{vem} console window, menus, dialog boxes, etc., to something smaller than the default. Also,

\texttt{Vem*background: antiqueWhite}

changes the background in the \texttt{vem} console window and dialog boxes to the color “antique-White.”
2.14 Tk options

In Tycho, many of the user interface features are controlled through the preferences manager, which is available under the Tycho Help menu. In the older non-Tycho Tk windows, a number of user interface options are specified through Tk options rather than directly through X resources. These are defined in the file $PTOLEMY/lib/tcl/ptkOptions.tcl. One way to override these is to start pigi with a console window:

```
pigi -console
```

and in the console window, change the options. For example, the command

```
option add Pigi*background gray98
```

changes the dialog box backgrounds to a very light gray. This option was used to create the X window dumps used in this manual.

2.15 Multi-domain universes

The domain of a facet is set using the pigi “Edit:edit-domain” or “d” command. This command causes a checklist to appear listing all domains currently linked into the system. All examples in the SDF Demo palette are one-domain applications, using only SDF. Several examples of multi-domain applications can be found in the DDF and DE Demo palettes. It is instructive to explore these applications, using the edit-domain command at all levels of the hierarchy to see what domains are used. In addition, the section “Wormholes” on page 12-4 in the DE chapter contains a useful discussion on mixing the DE domain with other domains in Ptolemy.

Recall that a Wormhole in Ptolemy is a block that has a different domain on the outside than on the inside. In pigi, wormholes look exactly like galaxies -- in fact, they are both just facets with ports. The only difference is that the domain is different on the inside than on the outside. Thus, whether a particular facet compiles into a plain galaxy or a wormhole depends on whether it is referenced from an outer facet of the same domain or a different domain. You get a wormhole if the domains are different.

To build multi-domain applications, it is necessary to understand the models of computation in each domain, to ensure that application will behave consistently at the domain boundaries. For this, it is necessary to refer to the domain chapters in this user’s manual.

In some domains, it is possible to select one of several targets, which manage the execution of the domain in different ways. The target for a facet is set using the pigi “Edit:edit-target” or “T” command. This command causes a checklist to appear listing all targets available for the current domain. If a target is selected (rather than pushing “Cancel”), another dialog box appears containing whatever parameters the selected target may have. Both the current target selection and the parameters for it are recorded with the facet when you execute “save-window”.

If “edit-target” is executed in a galaxy facet (not a universe facet), then it offers a choice labeled <parent> in addition to the target(s) for the facet’s domain. This choice simply means “use the outer facet’s target selection and target parameters”. If you select this choice, then no target parameter dialog box appears.

The <parent> target choice is extremely important, because . If you choose anything other than <parent>, then your galaxy will always be compiled into a wormhole, so that it
can have a separate target from the outer galaxy or universe. A wormhole will be created even if you have in fact selected the same domain, same target and same target parameters as in the outer facet --- *pigil* doesn’t check. Thus, if you accidentally set the target choice to something besides `<parent>`, you’ll end up with wormholes rather than plain galaxies. This can cause unexpected behavior, because the semantics of an XXX-in-XXX wormhole aren’t necessarily the same as just embedding a galaxy into another galaxy. (DE domain, in particular, has some oddities with DE-in-DE wormholes as of this writing.) Even if the semantics are unaffected, a wormhole will be slower than a plain galaxy. So be careful to use `<parent>` in galaxies, unless you really intend to create a wormhole having a different target. In most cases, you only want to make specific target selections in universe facets.
